LIS 3353: IT Concepts for Information Professionals

Dr. Tameca Beckett

December 2, 2024

Introduction

In the modern world, the Information and Communication Technology (ICT) industry encompasses technologies and services used to manage and share information. Underneath the umbrella of ICT, a variety of technological products and services are provided, such as telecommunications, software, data management, cloud services, and IT support. The ICT industry serves a wide range of customers across the economy, from individual consumers to small and medium sized businesses (SMBs), to large enterprises and government agencies (OECD, 2004). In 2023, the ICT industry in the United States reached a worth of over $1.86 trillion and employed more than three million people (GlobeNewswire, 2024; Statista, 2023). As ICT technologies continue to rapidly evolve, the incorporation of Artificial Intelligence (AI) is reshaping how ICT companies provide services and optimize operations. The AI-driven systems and tools used within the ICT sector have changed the structure of the industry, from how business decisions are made to how systems are implemented. Machine learning and predictive analytics offer ICT businesses competitive advantages, but also introduce new challenges that raise questions about privacy and security. Collectively, Artificial Intelligence is transforming the ICT industry's infrastructure and business strategies, as well as introducing new ethical considerations.

The Role of AI in ICT Infrastructure

With AI increasingly becoming a central part of ICT infrastructure, productivity has been streamlined by systems that enhance efficiency, adaptability, and security. ITC systems of the past relied primarily on often cumbersome local hardware that had to be maintained by technicians (Kumar, 2024, p. 131). With modern advancements in AI technology, many ICT businesses have moved toward using or hosting cloud services which distribute computational

tasks across global networks of machines. These advancements in infrastructure allow for more convenient, adaptive ICT systems that can adjust to fluctuations in demand and manage available resources more efficiently (Haldorai et al., 2021, p. 563-567; Kumar, 2024, p. 131-133). Machine learning (ML), a subset of AI, employs real-time data analysis that facilitates predictive maintenance and resource optimization in these systems. By analyzing large amounts of data quickly, businesses and institutions can autonomously minimize operation costs and enhance productivity. For example, AI maintenance systems can predict potential network congestion or intervals of low demand, then proactively adjust to "scale dynamically," minimizing downtime and improving service quality around the clock (Haldorai, et al., 2021, p. 563; Kumar, 2024, p. 130). This technique is also applied to cybersecurity, where AI algorithms use machine learning to identify patterns in network activity and user behavior in order to thwart potential security risks and vulnerabilities (Haldorai, et al., 2021, p. 563). Fast, accurate implementations of predictive analytics via AI technology allows organizations to prevent or address problems before they escalate, saving time and money.

Business Implications of AI in ICT

Moreover, AI integration in ICT has revolutionized data analysis and granted businesses substantial competitive advantages, but its success relies heavily on the quality of the data and how it is used. Companies that utilize AI services for business analytics are able to gain insights that allow them to make informed business decisions and forecast trends, which has proven to be very effective (Kumar, 2024, p. 129-131). In fact, the modern revolution of data analytics has been so impactful that it is often referred to as "industry 4.0," or "the fourth industrial revolution" (Prokopowicz & Gołębiowska, 2021, p. 46; Tambare et al., 2021, p. 2-3). As Mathur writes in "How AI and Analytics Can Encourage Innovation," AI primarily informs analytical

approaches in four ways: “specification of goals, data collection and preparation, modeling, and value capture” (p. 41). To assist with capturing and evaluating the necessary information for these points of interest, the ICT industry offers various business intelligence software platforms. These platforms fall under the category of products known as “software as a service” (SAAS) (Kumar, 2024, p. 130). These platforms can be distributed as software packages to businesses and consumers, where AI plays a role in identifying business opportunities, detecting security threats, or quickly generating reports. Many SAAS products are designed to be convenient and user-friendly, such that even non-technical professionals can use them to get basic insights on data (Chang, 2014 as cited in Larson et al., 2016 p. 19-21). It follows that when trained on comprehensive, high-quality datasets, AI provides reliable insights that support improving a business’s ability to respond quickly to changes in market conditions and maintain cybersecurity. However, the effectiveness of any insights gleaned from AI analysis are highly dependent on the quality of the data. If the data is biased, outdated, or flawed, then it can inadvertently lead to poor decision-making. Further, even with quality data, improper training & incorrect utilization by non-technical users can lead to poor quality insights (Rana et al., 2022, p. 368-369). Rana et al. describe in “Understanding Dark Side of Artificial Intelligence (AI) Integrated Business Analytics […]” that “lack of governance, poor data quality, and inefficient training” can lead to unintentional consequences (p. 369).

Privacy, Ethics, and Regulatory Considerations

As a result, policy has emerged to address the ethical issues pertaining to AI use and data management in the ICT industry. The foundation of AI in ICT for businesses is in the incredibly large amounts of data that institutions collect, referred to as “big data.” AI technology is particularly suited for analyzing big data in a way that human beings cannot easily achieve

without machine assistance (Kathuria et al., p. 2-3). AI algorithms are used in data sets larger than one person could evaluate in a lifetime to predict consumer behavior and respond accordingly as a business. Insights collected from this mass of data are used to evaluate and predict trends, allowing companies to produce certain products, make them available at specific times, and stock them in specific places that generate optimal profits. Big data is collected around the clock, combining multiple different data sources such as the smartphones in consumers' pockets or the public facing, government-implemented cameras in China (Kathuria et al., 2024, p. 2-6). With the power of this kind of technology, consumers have reasonable concerns about how their data is used and collected, in many cases without their knowledge or consent (Haldorai et al., 2021, p. 567). Kathuria et al. write in "Protecting Data Privacy in the Age of AI […]" that some of the primary ways AI can infringe on an individual's data privacy are via: "re-identification and de-anonymization, opacity of secrecy and profiling, target marketing, [and] persistence surveillance […]" (p. 3). Each of these concerns has the potential to encroach on an individual's personally identifiable information (PII). PII includes details like a person's name, address, and even their biometric data, which are particularly vulnerable to breaches and misuse from massive data systems (Kathuria et al., 2024, p. 4; Heisenberg, 2025). Indeed, such catastrophic data breaches are a serious concern for the ICT industry. This raises questions about accountability: who is responsible when AI-driven processes go wrong, and who ultimately owns the data collected from individuals?

In 2018, the consulting firm Cambridge Analytica was found to have collected and used the personally identifiable information of over 87 million unknowing Facebook users. This event became a frequently-discussed incident of data misuse in the ICT industry known as the Facebook-Cambridge Analytica scandal. During the scandal, PII was collected in mass to form

psychological profiles for targeted political advertising. Not only was this invasive and dangerous, but it also reignited a global conversation on data ethics and regulations (Venturini and Rogers, 2019, Isaak and Hanna, 2018, Lapaire, 2018, as cited in González-Pizarro et al., 2022; Kathuria et al., 2024, p. 5). One of the earliest policy measures enacted to address data privacy in the modern age was the U.S. Privacy Act of 1974. It focused on ensuring that personal information held by federal agencies was transparent and accessible to individuals, providing safeguards against unauthorized access (Heisenberg, 2025). While the Privacy Act was revolutionary for its time, subsequent technological advancements in data collection, analysis, and AI revealed its limitations in private use of data. This led to the development of additional data regulations like the Health Insurance Portability and Accountability Act (HIPAA) of 1996. HIPAA expanded protections by regulating how healthcare providers and related organizations could handle sensitive health information (Duffourc et al., 2024; Heisenberg, 2025). Many companies operating globally had to adapt to these regulations, leading to widespread changes in data collection and processing practices in the ICT industry. Moving forward, as AI technology continues to exponentially advance, stronger international cooperation and updated legal regulations will be needed to balance business with consumer protections.

Future Directions and Implications for ICT Professionals

The future directions of AI in ICT yield both exciting opportunities and critical challenges, from the changing role of ICT professionals to the shifting technological frontier. As AI systems become deeply integrated into ICT, professionals in the field are tasked with mastering advanced skills while contending with the implications of technological advancements. Technological advancements, while significantly improving efficiency and innovation, come with trade-offs. Economically, the spreading prevalence of AI systems has the

potential to disrupt established job markets and industries. In the future, it is very possible and widely discussed that robotics and AI may replace human labor. Research indicates that up to 40% of existing low and medium-skill jobs in manufacturing and service industries could be automated by 2030, leaving millions without employment unless new job categories emerge (Arogyaswamy, 2020 p. 835). Socially, this raises concerns about inequality and the ability of economies to adapt to this transformation without significant global disruption. For the time being, though powerful, AI technology remains in its infancy on the grand scale of what may be possible. The possibility for AI to achieve artificial general intelligence (AGI), or human-equivalent intelligence, remains a prominent topic of discussion among researchers. Arogyaswamy (2020) writes in "Big Tech and Societal Sustainability[…]" that machine "superintelligence" may only be "a few decades [away]" (p. 837). The invention of AGI would require investment in ICT infrastructure capable of supporting unprecedented computational demands. AGI-focused ICT industries of the future would also radically transform the roles of professionals in the field. ICT specialists would need to adapt to managing and maintaining these highly complex systems while addressing the ethical and societal implications of AGI. As discussed, there are already insufficiently addressed concerns with automated accountability, decision making, and misuse of current technology. Any future advancements with desirable outcomes will depend on society's ability to create systems and policies that support the evolution of more intelligent AI.

Another of the most immediate concerns tied to the rapid growth of AI and ICT is the increasing energy demand. The technologies and systems that rely on complex computing and AI algorithms are powered by fossil fuels, which are rapidly depleting and harming the environment. For example, statistics show that energy consumed by one AI algorithm can

contribute to five cars' worth of CO2 emissions (Hao, 2019 as cited in Ahmad et al., 2021 p. 8). Emerging AI technologies like generative AI, natural language processing (NLP), and computer vision have all contributed to the trend in ever increasing global energy consumption. Arogyaswamy (2020) writes that almost every industry of modern life relies on now heavily AI-powered ICT, commenting on the challenge of sustaining ICT's energy demands that: "[s]ustainability is typically viewed as consisting of three forces[:] economic, social, and ecological, in tension with one another" (p. 829). In other words, it is a serious challenge to develop new systems that benefit society economically, socially, and ecologically without limiting or infringing on at least one of these three entities. Yet building a more sustainable power grid system to support rapidly advancing technologies is necessary. In transitioning away from fossil fuels, potential renewable energy sources, such as solar and hydrogen power, offer hopeful solutions to mitigate the ecological footprint of AI technologies. Additionally, AI itself could play a pivotal role in improving energy efficiency by optimizing power distribution, predicting energy demand, and identifying wasteful practices (Ahmad et al., 2021 p. 11-20). Much of the data already exists to utilize AI technologies in making more informed decisions about resource allocation and reducing environmental harm. As technology and energy demands continue to accelerate, a confrontation between power delivery, sustainability, and ethics is inevitable sooner rather than later.

Conclusion

It is evident that the integration of AI in the ICT industry is significantly reshaping its infrastructure, business strategies, and ethics. AI's pivotal role in ICT products and services illustrates its impact. From automating processes to enabling innovations in information and communication systems, AI has become an essential tool in enhancing the efficiency and

capabilities of modern ICT. In regard to business, AI's ability to analyze vast amounts of data in real time has unlocked new opportunities for decision-making and strategizing. This revolution in business intelligence not only strengthens the economy and competitive advantages for companies, but also redefines how companies impact the lives of individual consumers.

However, the rise of AI in ICT also introduces ethical challenges. The potential misuse of AI systems, whether intentional or accidental, poses significant risks to individual privacy and consumer trust. As algorithms become sophisticated beyond the point of feasible human analysis, questions about data security, accountability, and transparency have merit. Regulations must evolve along with AI's rapid advancements to ensure the responsible implementation of these technologies in a way that balances safeguarding individuals with promoting innovation.

Looking to the future, the ongoing evolution of AI presents both opportunities and challenges for the ICT industry. Professionals in ICT must adapt to emerging trends and remain technically informed to be competitive. As AI technologies continue to advance, the main challenges of the future will be in ensuring that innovation aligns with ethics and sustainability goals. By embracing continuous learning, addressing ethical concerns, and investing in sustainable systems, ICT professionals can work alongside AI technology to create a promising future.
